

Innovation in Bicycle and Pedestrian Counts

A Review of Emerging Technology

SUMMARY

To create better facilities for people walking and biking, and to locate these facilities where demand and need is the highest, transportation professionals need reliable data to guide decision-making. Historically, collecting active transportation data has been both time and resource intensive. Although many communities have established robust count programs, there are still funding, quality control, and data management limitations. New technologies are emerging that aim to change the way active transportation data is collected, making it less expensive and easier to collect, resulting in more reliable data. This report provides a review of these technologies and their applications.

Contributors: Hugh Louch, Brad Davis, Kim Voros, Kristen O'Toole, and Sam Piper, Alta Planning + Design

This white paper is based on research leading to online publication in Spring 2016. The report is based on findings as of this date.

Please note: Several companies are veterans of the automated data collection field. These companies' devices have served many communities. However, this white paper focuses on emerging technology. The report presents new or less well-known products and companies. The authors aim to provide an overview of these devices and will update the report as the field evolves.

Bike and pedestrian count programs have been established across the country, but they primarily rely on paper and pen to record data, which can be cumbersome to process.

INTRODUCTION

Rates of active transportation have increased nationally over the past fifteen years, driven by steady growth in better walking and bicycling infrastructure. As this trend continues, transportation professionals have become frustrated by a general lack of bike and pedestrian count data. Having access to more robust data is important for several reasons:

- » Data helps to determine where investments in walking and biking infrastructure are most needed
- » Data makes it possible to assess changes over time, draw conclusions about the impact of new facilities, and improve the design of future facilities
- » Data helps to quantify the benefits of walking and biking, which ultimately makes active transportation projects more competitive for funding

» A federal-level initiative, the US Department of Transportation's Mayor's Challenge for Safer People, Safer Streets, calls for improved walking and bicycling data collection

One of the most persistent challenges facing the bicycle and pedestrian field is the lack of usage and demand documentation. Without accurate and consistent count data, it is difficult to measure the positive benefits of investments in these forms of transportation, especially when compared to other modes, such as the private automobile. Fortunately, current and emerging technologies can capture and process non-motorized data efficiently and economically. This report provides a review of these technologies and how they can be integrated into bike and pedestrian count programs.

NATIONAL BIKE AND PEDESTRIAN DOCUMENTATION PROJECT

In 2004, Alta Planning + Design and the Institute of Transportation Engineers (ITE) Pedestrian and Bicycle Council established the National Bicycle & Pedestrian Documentation Project (NBPD).^{*} This nationwide effort provided a consistent model of data collection for use by planners, governments, and bicycle and pedestrian professionals. Before the program, there were few systematic and coordinated efforts to include bicycle and pedestrian movements in count data.

The NBPD specifies that standardized counts should occur twice a year, in the spring and the fall. Communities record activity at key locations during two-hour morning and afternoon 'peak-commute' periods on weekdays (Tuesdays, Wednesdays, or Thursdays). A Saturday count precedes or follows the official count dates. Typically, cities and towns enlist volunteers to staff the various locations. Since its inception in 2004, hundreds of cities and towns across the country have used this methodology to count bicycle and pedestrian activity within their communities. The NBPD project has succeeded in changing the way these cities and towns collect active transportation data. However, after nearly a decade of operation, challenges to the program have become apparent:

- » Two-hour AM and PM count periods provide invaluable data, but planners have difficulty making annualized assumptions from this data. A single day does not represent typical travel patterns. National Cooperative Highway Research Program (NCHRP) Report 797: Guidebook on Pedestrian and Bicycle Volume Data Collection found, "the error in estimating average annual bicycle traffic from two-hour, 12-hour, or even one-week counts can be up to 40%" (TRB, 2015, <http://www.trb.org/Main/Blurbs/171973.aspx>). Conversely, annualized vehicle count data is readily available. Annualized data is critical because it provides the ability to understand change and forecast trends. Without comparable annualized walk and bike figures, it is more difficult to make a case for investments in these modes.
- » Bicyclists and pedestrians have different travel habits than motor vehicles – trips tend to be shorter and distributed throughout the day. These factors make it more difficult to reliably capture their activity with two hour counts.

- » Enlisting volunteers to staff counts is time consuming, and organizing volunteers can be a burden for municipal employees who have limited time and budget available to dedicate to this important task.
- » Non-motorized counts are still primarily conducted with paper and pen. Staff digitize these records after data collection. This process can be time consuming, making data analysis a tedious task.

^{}Now called the ITE Pedestrian and Bicycle Standing Committee.*

Alta is not advocating for the cessation of manual count programs. Alta recognizes that integrating technology into count programs will be a gradual process that will take time. Manual programs have many benefits, including the following, which are listed in no particular order:

- They are great community building exercises that help to engage advocates and highlight the importance of walking & biking.
- Some communities may not have the resources to purchase and install automated counters, making manual count programs the most economical option. In the event that an automated program cannot be implemented, manual counts should continue to be conducted as usual.
- They can quickly produce data in locations of interest (e.g., high-crash locations, corridors that are under review for design changes).
- They can be combined with automated technology, such as mobile applications that replace clipboards with counting boards or screens.
- They are used before deploying automated devices to study a given location's suitability for automated counters. They are also used after automated devices are installed to calibrate and confirm data collected through automated means.

SHORT- AND LONG-TERM COUNT TECHNOLOGY FROM EXISTING LITERATURE AND PRACTICE

NCHRP Report 797: Guidebook on Pedestrian and Bicycle Volume Data Collection compares several types of automated equipment designed to count people walking and bicycling. The report aims to compare different solutions’ accuracy, precision, and suggested uses. Due to federal funding, the NCHRP report cannot specify which brands were tested to create the report. This section discusses selected technology types discussed within the NCHRP report and similar references, such as the FHWA Traffic Monitoring Guide (TMG).

SHORT- AND LONG-TERM PEDESTRIAN COUNTERS

Pedestrian counters often use an infrared beam to count people passing a counting point. Active infrared devices are composed of a transmitter and a receiver. An infrared beam travels through the middle, undetected by the human eye. The device counts a person when they break the beam.

Similarly, passive infrared devices project an infrared beam from a fixed point. Anyone within the beam’s cone shape is counted. TrailMaster, TRAFx, and EcoCounter are three commonly-used infrared count device manufacturers.

SHORT- AND LONG-TERM BICYCLE COUNTERS

Bicycle counters come in a number of shapes and sizes. Most cities with count programs use one of a handful of data collection options. Pneumatic tubes are appropriate for short-duration counts. They sit on the surface of a roadway and record bicycle traffic. Specialized filters allow the devices to “ignore” motorized traffic that passes over the tubes. EcoCounter and MetroCount are two companies that create bicycle-specific pneumatic tubes as well as other types of traffic monitoring technology. Longer duration counts are possible by using a number of technology types including inductive loops, magnetometers, piezoelectric strips, radar sensors, and thermal imaging. The NCHRP Report 797, Traffic Monitoring Guide, and NBPD outline these and other types of technology. Inductive loops, magnetometers, piezoelectric strips, and radar sensors are embedded in the pavement and detect bicycles as they pass the respective sensor. Thermal imaging cameras are affixed to existing poles within the right of way and capture bicyclists’ heat signature as they ride within a counting zone. Video imaging is suitable for long- or short- duration count periods. Subsequent sections will discuss emerging thermal and video imaging solutions.

Table 1. Counter Types from Existing Literature and Practice

| Technology Type | Common Manufacturers | User Type | Duration | Typical Uses |
|-------------------------------|--|--|---------------|----------------------------------|
| Infrared (Active and Passive) | <ul style="list-style-type: none">• TRAFx• EcoCounter• TrailMaster |  <i>Does not automatically distinguish between peds/bikes.</i> | Short or long | Sidewalk or shared-use path |
| Pneumatic Tubes | <ul style="list-style-type: none">• EcoCounter• MetroCount• TRAFx• Road Sys |  | Short | On-road |
| Inductive Loop | <ul style="list-style-type: none">• EcoCounter• Road Sys |  | Long | On-road or paved shared-use path |
| Magnetometer | <ul style="list-style-type: none">• TRAFx |  | Long | Shared-use path |
| Piezoelectric | <ul style="list-style-type: none">• MetroCount |  | Long | On-road |
| Radar Sensors | <ul style="list-style-type: none">• Sensys Networks |  | Long | On-road |
| Thermal Imaging | <ul style="list-style-type: none">• FLIR |  | Long | On-road |
| Video Imaging | <ul style="list-style-type: none">• Miovision |  | Short or long | On-road |

Again, the NBPD has been an extremely successful program. Countless communities have used the data to build better facilities for walking and biking. Many of the program's issues are due to it being a product of its time; in 2004, when it was launched, paper and pen was the only low-cost option for data collection (Facebook had its first birthday in 2004, the first iPhone was not released until 2007, and the first iPad not

until 2010). The wireless tech-revolution that has occurred over the past 10 years has ushered in new tools to facilitate non-motorized data collection. As these products scale up, their prices fall, creating a marketplace that is changing the way we can monitor traffic.

INNOVATIVE COUNTING TECHNOLOGIES

Several cities are leading the way in using mobile devices to measure increasing levels of bicycle traffic. Several others would like to retire their clipboards and install higher-tech, automated machines. Until very recently, such programs were cost prohibitive. New technologies can reduce the cost of non-motorized data collection, analysis, and visualization. These market disrupters have the potential to provide

a variety of services, while frequently costing a fraction of traditional counting equipment. The following section outlines several services and corresponding technological solutions. The technologies that are emerging can be grouped into the categories listed below, and the graphic on page six summarizes the technologies reviewed.

Device Accuracy:

No independent authority has yet conducted a peer review of these devices' accuracy. At this time, the devices offer varying margins of error. Interested parties should contact the device suppliers to learn more about potential devices and their precision and accuracy.

Device Cost:

Device costs vary based on a number of factors. Costs are based on the price of purchasing counting units, but may also include additional charges for data processing (i.e., an hourly processing rate). Some companies allow users to utilize their own, pre-existing cameras as counting devices. In these cases, prices will differ, since they may not involve data processing but not hardware purchase costs.

INNOVATIVE COUNTING TECHNOLOGIES

Alta Planning + Design has been at the forefront of non-motorized data collection since its co-establishment of the National Bike and Pedestrian Documentation Project in 2004. New technologies are emerging that make it easier and cheaper to collect bike and ped data. Alta is assessing these technologies. The most promising are listed below, grouped by type. The relative cost of each is also identified.

MOBILE TECHNOLOGY

Mobile applications and devices can harness human action to count a variety of road users, track their travel, and measure the quality of transportation infrastructure.

COUNTERPOINT (APP BASED COUNTING SOFTWARE)

Counterpoint is a mobile app designed to “make it easy to count traffic.” It provides the ability to make your own counting site or add to an existing site. Tap specific buttons to record who uses the public realm during your counting session. The app also boasts robust traffic categories that are more nuanced than traditional pen and paper tallies, including user-friendly options such as “baby in stroller”, “oversized bike”, and “visually impaired pedestrian.”

STRAVA METRO, CYCLETRACKS, AND CYCLE ATLANTA (GPS ENABLED ROUTE TRACKERS)

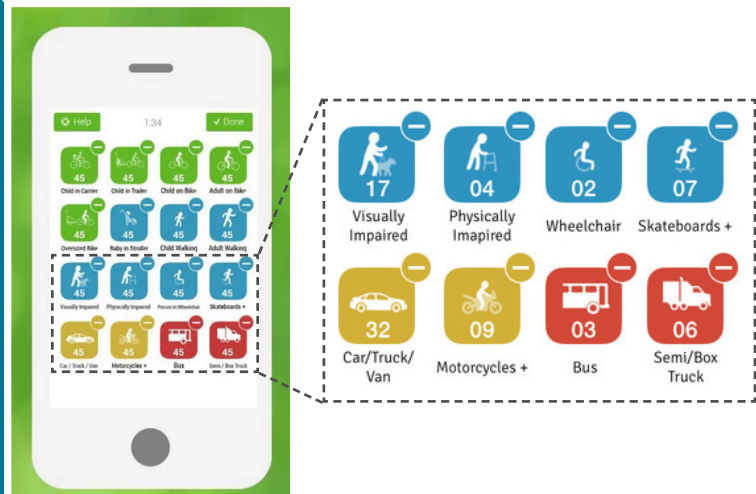

Many people who bike or jog use Strava or related apps to track their distance, speed, and route. Portland Bureau of Transportation (PBOT) made history a few years ago when they decided to purchase a large Strava-collected data set. Cities around the world have since purchased Strava data sets to get a sense of their cities’ own trip patterns.

Although the data tends to capture recreational riders, whose gender and ethnicity do not typically represent the overall population, the data is useful to generally determine what routes people are riding. Strava is currently working with municipalities to identify the shortcomings of the data and tailor it better to cities’ needs. Eighteen cities have adapted a similar app, CycleTracks, originally created for data collection in San Francisco in 2010. The application’s code is open

source (<http://github.com/sfcta>). Cycle Atlanta (cycleatlanta.org) was created to help the City make decisions about locations for new bicycle infrastructure. App users could also submit data about their experience along a given route.

RIDE REPORT (GPS ENABLED ROUTE TRACKER + HARDWARE)

Another app, Ride Report, shares a similar mission to Strava. Once downloaded, the app automatically logs any bicycle trip. Over 20,000 people in Portland have used the app, generating a continuously updating map that displays the ease or stress of bicycling the city's streets. Ride Report's creators are developing bicycle counting hardware to augment their mobile application. The device combines a magnetometer and an infrared camera to count bicyclists. The application automatically logs other app users who pass within 20 to 30 feet of the device. The developing device uses cloud-based

data storage instead of expensive physical storage. According to Bike Portland, the Portland Bureau of Transportation (PBOT) purchased 200 of the devices in 2015.

AIRSAGE (ANONYMOUS DATA COLLECTION SOFTWARE)

What if the data could originate from common, household devices independent of their owners' guidance? Enter, AirSage, which uses ordinary cellphone signals to generate overall traffic patterns for all roadway users. According to the company website, "AirSage generates billions of anonymous location data points, transforming terabytes of signaling data every day into valuable, relevant and accessible information." However, the current technology makes it difficult to separate the data according to form of transportation.

| Cost | \$\$ |
| Installation | Easy |
| Data Extraction | Online Dashboard |

AirSage's process of collecting and analyzing cell phone data (Source: airsage.com)

PLACEMETER (VIDEO COUNTING SOFTWARE)

Placemeter, a company that emerged in 2012, turns video footage from any camera (including cell phones) into pedestrian, bicycle, and car movement data. First, users attach an existing security camera or a Placemeter Sensor in a window over the preferred measuring point. Placemeter defines a “Measurement Point” as a sidewalk, street, or storefront, where one wishes to measure bicycle, pedestrian, or vehicle activity. Since measurement points cannot currently distinguish between forms of transportation; users must purchase one screenline per mode of transportation. Measuring people walking, bicycling, and driving would therefore require three screenlines. After installation, the company turns measurement point video footage into data displayed on an online dashboard or emailed as a downloadable file. Placemeter can continue ongoing measurement using the Placemeter Sensor or live

security cameras. In addition to travel volumes, Placemeter can measure walking direction and store visits, and it is particularly well suited for locations where continuous count data is desired. The second generation Placement Sensor is expected in 2016. One drawback of the technology is that it requires a WiFi connection.

FLIR SYSTEMS (THERMAL SENSORS)

FLIR Systems, Inc. produces thermal imaging devices capable of long-term detection and counting of people walking, biking, and driving. Thermal sensors operate similarly to video sensors. While both types of devices capture imagery, thermal sensors generate images based on objects' and people's naturally-occurring infrared radiation. Thermal cameras do not need natural light to produce imagery. Therefore, they are less vulnerable to occlusion than video.

PLACEMETER

| | |

INEXPENSIVE HARDWARE

WAYCOUNT (PNEUMATIC TUBE COUNTER)

WayCount, based in New York, offers three DIY-type models. Each device uses pneumatic tubes and inexpensive, easily portable components to count bikes and cars. WayCount produces three devices: Lite, Aluminum, and Hi-Viz. The Lite model is \$199. The Aluminum device is \$200 plus freight. WayCount Aluminum requires a minimum purchase of 250 units. WayCount Hi-Viz features a screen with 6" tall LED letters, which makers say can be viewed 100' away. The screen lets bicyclists, passersby, and drivers see the number of bicyclists counted in real time since the session began. Each of the WayCount devices can collect continuous data throughout a 24-hour period.

NUMINA (WIRELESS SENSOR)

Numina, an emerging product from CTY, used the Knight Foundation Prototype Fund to develop a device to track people walking, biking, and driving. The start-up aims to produce an inexpensive sensor, easily installed on existing light poles, without the need for special tools or know-how.

The 2015 Association of Pedestrian and Bicycle Professionals (APBP) conference proved the perfect testing ground for the fledgling device. Conference attendees provided feedback to improve the prototype. With time, Numina aims to measure noise pollution, air quality, and green space, in relation to traffic counts.

COUNTING AND MORE

Some devices go beyond counts data collection to investigate other characteristics of an urban space. The Array of Things (AoT) project team is developing sensors to count people in public spaces. They are also working to collect place-related data such as air quality and other indicators.

AoT, led by Argonne National Laboratory and the University of Chicago, is currently working with a \$3.1 million grant from the National Science Foundation to develop an “urban-scale ‘instrument’” to track a laundry list of freely-available, public data. The project team and the City of Chicago plan to install 50 sensor nodes to streetlights in early 2016. By 2017, the number will grow to 500.

INTERESTED IN LEARNING MORE?

The range of technologies shown below can help you create powerful datasets to inform transportation planning in your community. Alta Planning + Design offers comprehensive services to develop custom tailored active transportation count programs. We can help you determine which tools are the most appropriate, identify count locations, and coordinate installation. Our analytics team can also collect the data and create compelling visuals to make it useful for decision makers. Please contact us with any questions you have about instituting a tech-driven count program today.

ABOUT THE AUTHORS

Kristen O'Toole | kristenotoole@altaplanning.com

Kristen assists in managing a variety of bicycle and pedestrian projects ranging from data collection and analysis to master planning. She guides cities, regions, and states through the data collection process with the ultimate goal of deciphering data to support their current and future visions.

Sam Piper | sampiper@altaplanning.com

Sam has focused his career on developing better infrastructure for active modes of transportation. He has extensive experience leading long-term count programs and visualizing bike and pedestrian data. He enjoys using technology to make sense of our surroundings and to facilitate decision making.
